Terminology

- The higher-order functions like **map()** are "lazy"

  - They only create objects when there's a consumer

  - We use **list()** (or **tuple()**) to consume values and create a sequence object

    - This forces **map()** (or **filter()**) to actually get up off the couch and compute something

- Most functions we write are are "eager"

  - They immediately create an object
